STATEMENT

In the matter of US patent application 09/673,274 (Lamberty *et al*)

I, Bruno Flesselles,

declare that I am conversant with the English and French languages, and that to the best of my knowledge and belief, the following is an accurate translation of patent application FR 98/04933, the priority of which is claimed by the above application.

Date: January 13, 2004

A handwritten signature in black ink, appearing to read 'Bruno Flesselles'.

Bruno FLESSELLES

GENE ENCODING HELIOMICINE AND ITS USE

The subject of the present invention is a new cysteine-rich peptide called heliomicine, its use as a medicament and the compositions containing it, a DNA
5 sequence encoding this peptide, a vector containing it for the transformation of a host organism and the method of transforming the said organism.

The invention relates more particularly to the transformation of plant cells and of plants, the
10 heliomicine produced by the transformed plants conferring on them resistance to diseases, in particular of fungal origin.

There is currently an increasing need to make plants resistant to diseases, in particular fungal
15 diseases, in order to reduce or even avoid having to use treatments with antifungal protection products, in order to protect the environment. One means of increasing this resistance to diseases consists in transforming plants so that they produce substances
20 capable of providing their defence against these diseases.

In the field of human health, opportunistic fungal infections exist for which no truly effective treatment currently exists. In particular, this is the
25 case for certain serious invasive mycoses which affect hospital patients whose immune system is suppressed following a transplant, a chemotherapy or HIV infection. Compared with the antimicrobial agent

arsenal, the current range of antifungal agents is very limited. A real need therefore exists to characterize and develop new classes of antifungal substances.

Various substances of natural origin, in particular peptides, are known which exhibit bactericidal or fungicidal properties, in particular against the fungi responsible for plant diseases. However, a first problem consists in finding such substances which not only can be produced by transformed plants, but which can still preserve their bactericidal or fungicidal properties and confer them on the said plants. For the purposes of the present invention, bactericidal or fungicidal is understood to mean both the actual bactericidal or fungicidal properties and the bacteriostatic or fungistatic properties.

Cysteine-rich peptides are also known which exhibit bactericidal or bacteriostatic activities, but which do not exhibit fungicidal or fungistatic activity. Another problem consists in finding a cysteine-rich peptide which exhibits a high fungicidal or fungistatic activity compared with the peptides of the state of the art.

Helioincine is a peptide isolated from the haemolymph of the lepidopteron *Heliothis virescens* which exhibits fungicidal activity against the fungi responsible for plant diseases and the fungi of human

or animal pathology. After having first synthesized the gene for heliomicine, it was also found that it could be inserted into a host organism, such as a yeast or a plant, so as to express heliomicine and either produce
5 purified or nonpurified heliomicine, or confer on the said host organism properties of resistance to fungal diseases, providing a particularly advantageous solution to the problems set out above.

The subject of the invention is therefore
10 first heliomicine, its use as a medicament or in agrochemistry for the protection of plants, the compositions comprising it, a nucleic acid fragment encoding heliomicine, a chimeric gene comprising the said fragment encoding heliomicine as well as
15 heterologous regulatory elements at the 5' and 3' positions which can function in a host organism, in particular in yeasts or plants and a vector for transforming the host organisms containing this chimeric gene, and the transformed host organism. It
20 also relates to a transformed plant cell containing at least one nucleic acid fragment encoding heliomicine and a plant resistant to diseases containing the said cell, in particular which is regenerated from this cell. It finally relates to a method of transforming
25 plants to make them resistant to diseases into which a gene encoding heliomicine is inserted by means of an appropriate vector. It finally relates to a method of

preparing heliomicine by transformed host organisms.

Heliomicine is understood to mean according to the invention any peptide comprising essentially the peptide sequence of formula (I) below,

5

in which:

10 Xaa is -NH_2 or a peptide residue comprising from 1 to 10 amino acids, preferably from 1 to 6 amino acids,

Xab is a peptide residue comprising from 1 to 10 amino acids, preferably 10,

15 Xac is a peptide residue of 3 amino acids,

Xad is a peptide residue comprising from 1 to 9 amino acids, preferably 9,

Xae is a peptide residue comprising from 1 to 7 amino acids, preferably 7,

20 Xaf is a peptide residue of 1 amino acid, and

Xag is -OH or a peptide residue comprising from 1 to 5 amino acids, preferably 1 or 2 amino acids.

Advantageously,

Xaa represents the following peptide sequence Xaa'-Gly-
25 Xaa"- in which Xaa' represents NH_2 or a peptide residue comprising 1 to 9 amino acids, preferably 1 to 5 amino acids, and Xaa" represents a peptide residue comprising

at least one amino acid, preferably chosen from Leu, Ile, Val, Pro, Ser or Thr, and/or

Xab represents the following peptide sequence -Val-Xab'-Asp-, in which Xab' represents a peptide residue
5 comprising from 0 to 8 amino acids, preferably 8, and/or

Xac represents the following peptide sequence -Asn-Xac'-Glu-, in which Xac' represents a peptide residue comprising 1 amino acid, and/or

10 Xad represents the following peptide sequence -Lys-Xad'-Gly-His-, in which Xad' represents a peptide residue comprising from 0 to 6 amino acids, preferably 6, and/or

Xae represents the following peptide sequence
15 -Gly-Xae'-Asn-, in which Xae' represents a peptide residue comprising from 0 to 5 amino acids, preferably 5, and/or

Xaf represents one of the following amino acids -Trp-, Phe, Leu, Ile or Val and/or

20 Xag represents the following peptide sequence -Glu-Xag' in which Xag' represents OH or a variable residue having a sequence comprising from 1 to 4 amino acids, preferably 1 amino acid.

According to a preferred embodiment of the
25 invention, Xaa or Xaa' comprise at least one basic amino acid, and/or Xad or Xad' comprise at least one basic amino acid. Advantageously, Xad or Xad' comprise

1, 2, 3 or 4 basic amino acids.

Basic amino acids are understood to mean more particularly according to the invention the amino acids chosen from lysine, arginine or homoarginine.

5 According to a more preferred embodiment of the invention, Xaa represents the following peptide sequence NH_2 -Asp-Lys-Leu-Ile-Gly-Ser-, and/or Xab represents the following peptide sequence -Val-Trp-Gly-Ala-Val-Asn-Tyr-Thr-Ser-Asp-, and/or Xac represents the
10 following peptide sequence -Asn-Gly-Glu-, and/or Xad represents the following peptide sequence -Lys-Arg-Arg-Gly-Tyr-Lys-Gly-Gly-His-, and/or Xae represents the following peptide sequence -Gly-Ser-Phe-Ala-Asn-Val-Asn-, and/or Xaf represents the following amino acid
15 -Trp- and/or Xag represents the following peptide sequence -Glu-Thr-OH.

 According to a more preferred embodiment of the invention, the heliomicine is the peptide represented with its coding sequence by the sequence
20 identifier No. 2 (SEQ ID NO 2). The same sequence is described, corresponding to amino acids 6 to 49 of the sequence identifier No. 1 (SEQ ID NO 1) with a different coding sequence.

 The NH_2 -terminal residue may exhibit a post-
25 translational modification, for example an acetylation, likewise the C-terminal residue may exhibit a post-translational modification, for example an amidation.

Peptide sequence comprising essentially the peptide sequence of general formula (I) is understood to mean not only the sequences defined above, but also such sequences comprising at either of their ends, or
5 at both ends, peptide residues necessary for their expression and targeting in a host organism. Host organism is understood to mean any organism comprising at least one cell, whether microorganisms, in particular a yeast or a bacterium, or alternatively
10 plant cells or alternatively higher organisms such as plants.

This may be in particular a "peptide-heliomicine" fusion peptide whose cleavage by the enzymatic systems of the host organism allows the
15 release of heliomicine, heliomicine being defined above. The peptide fused with heliomicine may be a signal peptide or a transit peptide which makes it possible to control and orient the production of heliomicine in a specific manner in a portion of the
20 host organism, such as for example the cytoplasm, the cell membrane, or in the case of plants in a particular type of cell compartment or of tissues or in the extracellular matrix.

According to one embodiment, the transit
25 peptide may be a signal for chloroplast or mitochondrial homing, which is then cleaved in the chloroplasts or the mitochondria.

According to another embodiment of the invention, the signal peptide may be an N-terminal signal or "prepeptide", optionally in combination with a signal responsible for retaining the protein in the endoplasmic reticulum, or a peptide for vacuolar homing or "propeptide". The endoplasmic reticulum is the site where the operations for processing the protein produced, such as for example the cleavage of the signal peptide, are performed by the "cellular machinery".

The transit peptides may be either single, or double, and in this case optionally separated by an intermediate sequence, that is to say comprising, in the direction of transcription, a sequence encoding a transit peptide of a plant gene encoding a plastid localization enzyme, a portion of sequence of the N-terminal mature part of a plant gene encoding a plastid localization enzyme, and then a sequence encoding a second transit peptide of a plant gene encoding a plastid localization enzyme, as described in application EP 0 508 909.

As transit peptide useful according to the invention, there may be mentioned in particular the signal peptide of the tobacco PR-1 α gene described by Cornelissen et al., represented with its coding sequence by the sequence identifier No. 2, in particular when heliomicine is produced by plant cells

or plants, or the precursor of factor Mat $\alpha 1$ when heliomicine is produced in yeasts.

The fusion peptide "MF $\alpha 1$ /heliomicine" with the five residues of the propeptide of factor MF $\alpha 1$ (Ser-Leu-Asp-Lys-Arg), which are situated at the N-terminal position, and its coding sequence are part of the present invention, described in particular by the sequence identifier No. 1 (SEQ ID NO 1), corresponding to amino acids 1 to 49.

The "PR-1 α signal peptide-heliomicine" fusion peptide and its coding sequence are also part of the present invention, described in particular by the sequence identifier No. 3.

According to a preferred embodiment of the invention, the cysteine residues of the peptide of formula (I) form at least one intramolecular disulphide bridge, preferably three disulphide bridges. According to a preferred embodiment of the invention, the disulphide bridges are established between the cysteine residues 1 and 4, 2 and 5, and 3 and 6.

Heliomicine is a peptide which is particularly active against fungi and yeasts, and may as such be used preventatively or curatively to protect various organisms against fungal attacks. The present invention therefore relates to heliomicine as a medicament. It also relates to the use of heliomicine for the treatment of plants against fungal attacks, by

applying heliomicine directly to the said plants.

The present invention also relates to a composition comprising heliomicine and an appropriate vehicle. The first quality of the appropriate vehicle is not to substantially degrade the heliomicine in the composition, and not to reduce the bactericidal and fungicidal properties of the heliomicine. This composition may be a cosmetic composition and in this case the appropriate vehicle is cosmetically acceptable (suitable in addition for application to the skin or the exoskeleton), or a pharmaceutical composition for a therapeutic use and in this case the appropriate vehicle is pharmaceutically acceptable, appropriate for administration of heliomicine by the topical route per os or by injection, or alternatively an agrochemical composition and in this case the appropriate vehicle is agrochemically acceptable, appropriate for application to plants or in the vicinity of plants, without damaging them.

The present invention also relates to a nucleic acid fragment, in particular DNA, natural or synthetic, encoding the heliomicine defined above, including the "peptide-heliomicine" fusion peptide defined above. It may be according to the invention a fragment which is synthesized or which is isolated from the lepidopteron *Heliothis*, or alternatively a derived fragment, suitable for the expression of heliomicine in

the host organism where the peptide will be expressed. The nucleic acid fragment may be obtained according to standard isolation and purification methods, or alternatively by synthesis according to the customary
5 methods of successive hybridizations of synthetic oligonucleotides. These techniques are in particular described by Ausubel *et al.*

According to the present invention, "nucleic acid fragment" is understood to mean a nucleotide
10 sequence which may be of the DNA or RNA type, preferably of the DNA type, in particular double-stranded.

According to one embodiment of the invention, the nucleic acid fragment encoding heliomicine
15 comprises the DNA sequence described by bases 16 to 147 of the sequence identifier No. 1 (SEQ ID NO 1), or by the sequence identifier No. 2 (SEQ ID NO 2), in particular the coding portion of this sequence corresponding to bases 1 to 132, a homologous sequence
20 or a sequence complementary to the said sequence.

According to another embodiment of the invention, the nucleic acid fragment encoding the "peptide-heliomicine" fusion peptide comprises the DNA sequence described by the sequence identifier No. 1
25 (SEQ ID NO 1) or that described by the sequence identifier No. 3 (SEQ ID NO 3), in particular the coding portion corresponding to bases 3 to 224, a

homologous sequence or a sequence complementary to the said sequences.

"Homologue" is understood to mean according to the invention a nucleic acid fragment exhibiting one or more sequence modifications relative to the nucleotide sequence described by the sequence identifiers Nos. 1, 2 or 3 and encoding heliomicine or the "peptide-heliomicine" fusion peptide. These modifications may be obtained according to the customary mutation techniques, or alternatively by choosing the synthetic oligonucleotides used in the preparation of the said sequence by hybridization. In the light of the multiple combinations of nucleic acids which may lead to the expression of the same amino acid, the differences between the reference sequence described by the sequence identifiers Nos. 1, 2 or 3 and the corresponding homologue may be substantial, all the more so since small-sized DNA fragments are involved which can be produced by chemical synthesis. Advantageously, the degree of homology will be at least 70% compared with the reference sequence, preferably at least 80%, more preferably at least 90%. These modifications are generally neutral, that is to say that they do not affect the primary sequence of the resulting heliomicine or fusion peptide.

The present invention also relates to a chimeric gene (or expression cassette) comprising a

coding sequence as well as heterologous regulatory elements at the 5' and 3' positions capable of functioning in a host organism, in particular plant cells or plants, the coding sequence comprising at least one DNA fragment encoding heliomicine or the "peptide-heliomicine" fusion peptide as defined above.

Host organism is understood to mean any lower or higher, mono- or pluricellular organism into which the chimeric gene according to the invention may be introduced, for the production of heliomicine. It includes in particular bacteria, for example *E. coli*, yeasts, in particular of the genera *Saccharomyces* or *Kluyveromyces*, *Pichia*, fungi, in particular *Aspergillus*, a baculovirus, or preferably plant cells and plants.

"Plant cell" is understood to mean according to the invention any cell derived from a plant and capable of constituting undifferentiated tissues such as calli, differentiated tissues such as embryos, plant portions, plants or seeds.

"Plant" is understood to mean according to the invention any differentiated multicellular organism capable of photosynthesis, in particular monocotyledonous or dicotyledonous plants, more particularly crop plants intended or otherwise as animal or human food, such as maize, wheat, rape, soyabean, rice, sugarcane, beet, tobacco, cotton and

the like.

The regulatory elements necessary for the expression of the DNA fragment encoding heliomicine are well known to persons skilled in the art according to
5 the host organism. They comprise in particular promoter sequences, transcription activators, terminator sequences, including start and stop codons. The means and methods for identifying and selecting the regulatory elements are well known to persons skilled
10 in the art.

For the transformation of microorganisms such as yeasts or bacteria, the regulatory elements are well known to persons skilled in the art, and comprise in particular promoter sequences, transcription
15 activators, transit peptides, terminator sequences and start and stop codons.

To direct the expression and the secretion of the peptide in the yeast culture medium, a DNA fragment encoding heliomicine is integrated into a shuttle
20 vector which comprises the following elements:

- markers which make it possible to select the transformants. Preferably, the *ura-3* gene is used for yeast and the gene which confers resistance to ampicilline for *E. coli*,
- 25 - a nucleic sequence allowing the replication (replication origin) of the plasmid in yeast. Preferably, the replication origin of the yeast 2 μ

plasmid is used,

- a nucleic sequence allowing the replication (replication origin) of the plasmid in *E. coli*,
- an expression cassette consisting

5 (1) of a promoter regulatory sequence. Any promoter sequence of a gene which is naturally expressed in yeast may be used. Preferably, the promoter of the *S. cerevisiae* Mfa1 gene is used.

 (2) of a sequence encoding a signal peptide
10 (or prepeptide) in combination with a homing peptide (or propeptide). These regions are important for the correct secretion of the peptide. Preferably, the sequence encoding the pre-pro-peptide of the precursor of factor Mfa1 is used.

15 (3) of a polyadenylation or terminator regulatory sequence. Preferably, the terminator of *S. cerevisiae* phosphoglycerate kinase (PGK) is used. In the expression cassette, the sequence encoding heliomicine is inserted downstream of the pre-pro
20 sequence and upstream of the PGK terminator.

 These elements have been described in several publications including Reichhart et al., 1992, Invert. Reprod. Dev., 21, pp 15-24 and Michaut et al., 1996, FEBS Letters, 395, pp 6-10.

25 Preferably, yeasts of the *S. cerevisiae* species are transformed with the expression plasmid by the lithium acetate method (Ito et al., 1993, J.

Bacteriol, 153, pp 163-168). The transformed yeasts are selected on a selective agar medium which does not contain uracil. The mass production of transformed yeasts is carried out by culturing for 24 h to 48 h in
5 a selective liquid medium.

The transformation of microorganisms makes it possible to produce heliomicine on a larger scale. The present invention therefore also relates to a method of preparing heliomicine, comprising the steps of
10 culturing a transformed microorganism comprising a gene encoding heliomicine as defined above in an appropriate culture medium, followed by the extraction and total or partial purification of the heliomicine obtained.

Preferably, during the extraction of the
15 heliomicine produced by yeasts, the yeasts are removed by centrifugation and the culture supernatant is placed in contact with an acidic solution which may be a solution of an inorganic or organic acid, such as for example hydrochloric acid or acetic acid. The extract
20 obtained is then centrifuged at cold temperature at a speed of 4000 to 10,000 rpm at 4EC for 30 to 60 min.

The purification of heliomicine may be preceded by a step of fractionation of the supernatant obtained following the extraction step. Preferably,
25 during the fractionation step, the extract is deposited on the reversed phase in order to carry out a solid phase extraction. The washing of the molecules which

are soluble in water is carried out with a dilute acidic solution and the elution of the hydrophobic molecules with an appropriate eluant. Good results are obtained with trifluoroacetic acid for the washing and
5 an eluant containing increasing quantities of acetonitrile in dilute acidic solution.

Preferably, the purification of heliomicine is carried out in two stages: a cation-exchange HPLC followed by a reversed phase HPLC with a suitable
10 eluant which may be different from or identical to that of the preceding phase. The various steps of the purification are monitored by a test of inhibition of fungal growth in liquid medium. Preferably, the test is carried out with the fungus *Neurospora crassa*.

15 The sequence of the heliomicine produced by the transformed yeasts is analysed according to the method of sequencing by Edman degradation and by mass spectrometry. The structural characterization is carried out directly on the peptide produced, on the
20 peptide modified by reduction/alkylation as well as on fragments of the peptide. The peptide sequence and the molecular mass of the heliomicine produced were compared with those of the native heliomicine extracted from the haemolymph of *H. virescens*. The results show
25 that the two molecules have the same primary structure. The determination of the position of the disulphide bridges indicates that the arrangement of the

disulphide bridges is identical in both peptides, the native peptide and the one produced by the transformed microorganism.

The invention relates more particularly to
5 the transformation of plants. As promoter regulatory sequence in plants, it is possible to use any promoter sequence of a gene which is naturally expressed in plants, in particular a promoter of bacterial, viral or plant origin such as, for example, that of a gene for
10 the small subunit of ribulose-biscarboxylase/oxygenase (RuBisCO) or of a plant virus gene such as, for example, that of the cauliflower mosaic (19S or 35S CAMV), or a promoter which is inducible by pathogens such as the tobacco PR-1 α , it being possible to use any
15 known suitable promoter. Preferably, a promoter regulatory sequence is used which promotes the overexpression of the coding sequence constitutively or induced by attack by a pathogen, such as for example that comprising at least one histone promoter as
20 described in application EP 0,507,698.

According to the invention, it is also possible to use, in combination with the promoter regulatory sequence, other regulatory sequences which are situated between the promoter and the coding
25 sequence, such as transcription activators (enhancer), such as for example the translation activator of the tobacco mosaic virus (TMV) which is described in

application WO 87/07644, or of the tobacco etch virus (TEV) which is described by Carrington & Freed.

As polyadenylation or terminator regulatory sequence, there may be used any corresponding sequence
5 of bacterial origin, such as for example the *Agrobacterium tumefaciens* nos terminator, or alternatively of plant origin, such as for example a histone terminator as described in application EP 0,633,317.

10 According to the present invention, the chimeric gene may also be combined with a selectable marker suitable for the transformed host organism. Such selectable markers are well known to persons skilled in the art. They may include a gene for resistance to
15 antibiotics, or alternatively a gene for tolerance to herbicides for plants.

The present invention also relates to a cloning or expression vector for the transformation of a host organism containing at least one chimeric gene
20 as defined above. This vector comprises, in addition to the above chimeric gene, at least one replication origin. This vector may consist of a plasmid, a cosmid, a bacteriophage or a virus, which are transformed by the introduction of the chimeric gene according to the
25 invention. Such transformation vectors, according to the host organism to be transformed, are well known to persons skilled in the art and are widely described in

the literature.

For the transformation of plant cells or of plants, they may include in particular a virus which may be used for the transformation of developed plants
5 and which contains in addition its own elements for replication and expression. Preferably, the vector for transforming plant cells or plants according to the invention is a plasmid.

The subject of the invention is also a method
10 of transforming host organisms, in particular plant cells by integration of at least one nucleic acid fragment or a chimeric gene as defined above, which transformation may be obtained by any appropriate known means widely described in the specialized literature
15 and in particular the references cited in the present application, more particularly using the vector according to the invention.

A series of methods consists in bombarding cells, protoplasts or tissues with particles to which
20 DNA sequences are attached. Another series of methods consists in using, as means of transfer into plants, a chimeric gene inserted into an *Agrobacterium tumefaciens* Ti or *Agrobacterium rhizogenes* Ri plasmid.

Other methods may be used, such as
25 microinjection or electroporation, or alternatively direct precipitation by means of PEG.

Persons skilled in the art will make the

choice of the appropriate method according to the nature of the host organism, in particular of the plant cell or of the plant.

The subject of the present invention is also
5 the host organisms, in particular plant cells or plants, transformed and containing an effective quantity of a chimeric gene comprising a coding sequence for heliomicine defined above.

The subject of the present invention is also
10 the plants containing transformed cells, in particular the plants regenerated from the transformed cells. The regeneration is obtained by any appropriate means which depends on the nature of the species, as described for example in the above references.

15 For the methods of transforming plant cells and of regenerating plants, there may be mentioned in particular the following patents and patent applications: US 4,459,355, US 4,536,475, US 5,464,763, US 5,177,010, US 5,187,073, EP 267,159, EP 604,662, EP
20 672,752, US 4,945,050, US 5,036,006, US 5,100,792, US 5,371,014, US 5,478,744, US 5,179,022, US 5,565,346, US 5,484,956, US 5,508,468, US 5,538,877, US 5,554,798, US 5,489,520, US 5,510,318, US 5,204,253, US 5,405,765, EP 442,174, EP 486,233, EP 486,234, EP 539,563, EP
25 674,725, WO 91/02701 and WO 95/06128.

The present invention also relates to the transformed plants derived from the cultivation and/or

crossing of the above regenerated plants, as well as the seeds of transformed plants.

The plants thus transformed are resistant to certain diseases, in particular to certain fungal or
5 bacterial diseases. As a result, the DNA sequence encoding heliomicine may be integrated with the main objective of producing plants resistant to the said diseases, heliomicine being effective against fungal diseases such as those caused by *Cercospora*, in
10 particular *Cercospora beticola*, *Cladosporium*, in particular *Cladosporium herbarum*, *Fusarium*, in particular *Fusarium culmorum* or *Fusarium graminearum*, or by *Phytophthora*, in particular *Phytophthora cinnamomi*.

15 The chimeric gene may also comprise, and advantageously, at least one selectable marker, such as one or more genes for tolerance to herbicides.

The DNA sequence encoding heliomicine may also be integrated as a selectable marker during the
20 transformation of plants with other sequences encoding other peptides or proteins of interest, such as for example genes for tolerance to herbicides.

Such genes for tolerance to herbicides are well known to persons skilled in the art and are in
25 particular described in patent applications EP 115,673, WO 87/04181, EP 337,899, WO 96/38567 or WO 97/04103.

Of course the transformed cells and plants

according to the invention may comprise, in addition to the sequence encoding heliomicine, other heterologous sequences encoding proteins of interest such as other additional peptides which are capable of conferring on
5 the plant resistance to other diseases of bacterial or fungal origin, and/or other sequences encoding proteins for tolerance to herbicides and/or other sequences encoding proteins for resistance to insects, such as the *Bt* proteins in particular.

10 The other sequences may be integrated by means of the same vector comprising a chimeric gene, which comprises a first sequence encoding heliomicine and at least one other sequence encoding another peptide or protein of interest.

15 They may also be integrated by means of another vector comprising at least the said other sequence, according to the customary techniques defined above.

 The plants according to the invention may
20 also be obtained by crossing parents, one carrying the gene according to the invention encoding heliomicine, the other carrying a gene encoding at least one other peptide or protein of interest.

 Among the sequences encoding other antifungal
25 peptides, there may be mentioned that encoding drosomycin, which is described in patent application FR 2,725,992 and by Fehlbaum et al. (1994), and in

unpublished patent application FR 97 09115 filed on
24 July 1997, or that encoding androctonin which is
described in patent application FR 2,745,004 and in
unpublished patent application FR 97 10362 filed on
5 20 August 1997.

The present invention finally relates to a
method of cultivating transformed plants according to
the invention, the method consisting in planting the
seeds of the said transformed plants in a plot of a
10 field appropriate for cultivating the said plants, in
applying to the said plot of the said field an
agrochemical composition, without substantially
affecting the said seeds or the said transformed
plants, then in harvesting the cultivated plants when
15 they arrive at the desired maturity and optionally in
separating the seeds from the harvested plants.

Agrochemical composition is understood to
mean according to the invention any agrochemical
composition comprising at least one active product
20 having one of the following activities: herbicide,
fungicide, bactericide, virucide or insecticide.

According to a preferred embodiment of the
method of cultivation according to the invention, the
agrochemical composition comprises at least one active
25 product having at least one fungicidal and/or
bactericidal activity, more preferably exhibiting an
activity which is complementary to that of the

heliomicine produced by the transformed plants according to the invention.

Product exhibiting an activity which is complementary to that of heliomicine is understood to mean according to the invention a product exhibiting a complementary activity spectrum, that is to say a product which will be active against attacks by contaminants (fungi, bacteria or viruses) which are not sensitive to heliomicine, or alternatively a product whose activity spectrum covers that of heliomicine, completely or in part, and whose dose for application will be substantially reduced because of the presence of the heliomicine produced by the transformed plant.

The examples below make it possible to illustrate the present invention without however limiting its scope.

Example I: Isolation and characterization of heliomicine from the haemolymph collected from immunized larvae of the lepidopteron *H. virescens*

Example I.1: Isolation

1-1 Induction of the biological synthesis of an antifungal substance in the haemolymph of *H. virescens*

The 5th stage mature larvae of the lepidopteron *H. virescens* were immunized with the aid of a needle (30 ga) previously stuck into a pellet of Gram-positive (*M. luteus*) and Gram-negative (*E. coli* 1106) bacteria which is prepared from cultures carried

out in a Lauria-Bertani medium for 12 hours at 37EC.
The animals thus infected were kept individually in
tubes containing an agar-based nutrient medium for 24
hours between 20EC and 23EC. Before collecting the
5 haemolymph, the larvae were cooled on ice.

1-2 Preparation of the plasma

The haemolymph (about 30 μ l per larva) was
collected by excision of an abdominal appendage and
collected in 1.5-ml polypropylene microcentrifuge tubes
10 cooled on ice and containing aprotinin as protease
inhibitor (20 μ g/ml final concentration) and
phenylthiourea as melanization inhibitor (final
concentration of 20 μ M). The haemolymph (2 ml) thus
collected from the immunized larvae was centrifuged at
15 14,000 g for 1 min at 4EC in order to remove the
haemocytes. The haemolymph, free of blood cells, was
stored at -20EC up to its use.

1-3 Acidification of the plasma

After rapid thawing, the *H. virescens* plasma
20 was acidified to pH 3 with a 1% trifluoroacetic acid
solution. The extraction, under acidic conditions, of
the peptide was carried out for 30 min, with gentle
stirring, on an ice-cold bath. The extract obtained was
then centrifuged at 4EC for 30 min at 10,000 g.

25 1-4 Purification of the peptides

a) Prepurification by solid phase extraction

A quantity of extract equivalent to 2 ml of

haemolymph was deposited on a reversed-phase support, as marketed in the form of a cartridge (Sep-Pak™ C18, Waters Associates), equilibrated with acidified water (0.05% TFA). The hydrophilic molecules were removed by
5 a simple wash with acidified water. The elution of the peptide was carried out with a 40% acetonitrile solution prepared in 0.05% TFA. The fraction eluted at 40% of acetonitrile was dried under vacuum with the aim of removing the acetonitrile and the TFA and then it
10 was reconstituted in sterile ultrapure water before being subjected to the first purification step.

b) Purification by high-performance liquid chromatography (HPLC) on a reversed-phase column

- **first step:** the fraction containing the
15 peptide was analysed by reversed-phase chromatography on an Aquapore RP-300 C₈ semipreparative column (Brownlee™, 220 H 70 mm, 300 Å), the elution was carried out using a linear gradient of acetonitrile from 2 to 60% in 0.05% TFA over 120 minutes at a
20 constant flow rate of 1.5 ml/min. The fractions were collected manually, monitoring the variation of the absorbance at 225 nm and 254 nm. The fractions collected were dried under vacuum, reconstituted with ultrapure water and analysed for their antifungal
25 activity using the test described below.

- **second step:** the antifungal fraction corresponding to the peptide was analysed on an Aquapore RP-300 C₈.

reversed-phase analytical column (Brownlee™, 220 H 4.6 mm, 300 Å), using a biphasic linear gradient of acetonitrile from 2% to 22% over 10 min and from 22 to 32% over 50 min in 0.05% TFA with a constant flow rate of 0.8 ml/min. The fractions were collected manually, monitoring the variation of the absorbance at 225 nm and 254 nm. The fractions collected were dried under vacuum, reconstituted with ultrapure water and analysed for their antifungal activity under the conditions described below.

- **third step:** the antifungal fraction containing the peptide was purified to homogeneity on a Narrowbore Delta-Pak™ HPIC₁₈ reversed-phase column (Waters Associates, 150 H 2.2 mm) using a biphasic linear gradient of acetonitrile from 2% to 24% over 10 min and from 24 to 44% over 100 min in 0.05% TFA with a constant flow rate of 0.25 ml/min at a controlled temperature of 30EC. The fractions were collected manually, monitoring the variation of the absorbance at 225 nm. The fractions collected were dried under vacuum, reconstituted with filtered ultrapure water and analysed for their antifungal activity.

Example I.2: structural characterization of the peptide 2-1 Verification of purity by zonal capillary electrophoresis

The purity of the antifungal peptide was verified by zonal capillary electrophoresis on a 270-HT

model (PEApplied Biosystems division of Perkin Elmer).
1 nl of a 50 μ M solution of purified peptide was
injected with the aid of a vacuum into a silica
capillary (72 cm H 50 μ m) and the analysis was carried
5 out in a 20 mM citrate buffer at pH 2.5. The
electrophoresis was carried out at 20 kV from the anode
to the cathode for 20 min at 30EC. The migration was
recorded at 200 nm.

2-2 Determination of the number of cysteines :

10 reduction and S-pyridylethylation

The number of cysteine residues was
determined on the native peptide by reduction and
S-pyridylethylation. 100 pmol of native peptide were
reduced in 40 μ l of 0.5 M Tris-HCl buffer, pH 7.5
15 containing 2 mM EDTA and 6 M guanidinium chloride in
the presence of 2 μ l of 2.2 M dithiothreitol. The
reaction medium was placed under a nitrogen atmosphere.
After incubating for 60 min in the dark, 2 μ l of
freshly distilled 4-vinylpyridine were added to the
20 reaction which was then incubated for 10 min at 45EC in
the dark and under a nitrogen atmosphere. The
pyridylethylated peptide was then separated from the
constituents of the reaction medium by reversed-phase
chromatography using a linear gradient of acetonitrile
25 in the presence of 0.05% TFA.

2-3 Determination of the mass of the native peptide, of the S-pyridylethylated peptide and of the proteolysis

**fragments by MALDI-TOF (Matrix Assisted Laser
Desorption Ionization-Time of Flight) mass spectrometry**

The mass measurements were carried out on a Bruker Biflex MALDI-TOF mass spectrometer (Bremen,
5 Germany) in a positive linear mode. The mass spectra were calibrated externally with a standard mixture of peptides of known m/z , respectively 2199.5 Da, 3046.4 Da and 4890.5 Da. The various products to be analysed were deposited on a thin layer of α -cyano-4-
10 hydroxycinnamic acid crystals which is obtained by rapid evaporation of a solution saturated with ethanol. After drying under a moderate vacuum, the samples were washed with a drop of 0.1% trifluoroacetic acid before being introduced into the mass spectrum.

15 2-4 Sequencing by Edman degradation

The automated sequencing by Edman degradation of the native peptide, of the S-pyridylethylated peptide and of the various fragments obtained after the various proteolytic cleavages and the detection of the
20 phenylthiohydantoin derivatives were carried out on an ABI473A sequencer (PEApplied Biosystems division of Perkin Elmer).

2-5 Proteolytic cleavages

**- Confirmation of the peptide sequence in the C-
25 terminal region**

200 pmol of reduced and S-pyridylethylated peptide were incubated in the presence of 5 pmol of

endoproteinase-Lys-C (Acromobacter protease I, specific cleavage of the lysine residues on the C-terminal side, Takara, Otsu) according to the conditions recommended by the supplier (10 mM Tris-HCl, pH 9, in the presence of 0.01% Tween 20). After stopping the reaction with 1% TFA, the peptide fragments were separated by reversed-phase HPLC on a Narrowbore Delta-Pak™ HPIC₁₈ type column (Waters Associates 150 H 2 mm) in a linear gradient of acetonitrile from 2 to 60% over 80 min in 0.05% TFA with a flow rate of 0.2 ml/min and a constant temperature of 37EC. The fragments obtained were analysed by MALDI-TOF mass spectrometry and the peptide corresponding to the C-terminal fragment was sequenced by Edman degradation.

15 - Determination of the arrangement of the disulphide bridges by proteolysis with thermolysin

The native peptide (8 µg) was incubated for 1 hour in the presence of 4 µg of thermolysin (Boehringer Mannheim, thermolysin/peptide ratio, 1/2 by weight : weight) at 37EC in 0.1 M MES (N-ethylmorpholine) buffer at pH 7 in the presence of 2 mM CaCl₂. The reaction was stopped by addition of formic acid and the reaction products were immediately separated by reversed-phase chromatography on a Narrowbore Delta-Pak™ HPIC₁₈ column (Waters Associates, 150 H 2.2 mm) in a linear gradient of acetonitrile from 2 to 50% over 100 min in 0.05% TFA at the flow rate of 0.2 ml/min at 30EC preceded by an

isocratic step at 2% acetonitrile over 10 min. The fragments obtained were analysed by MALDI-TOF mass spectrometry and sequenced by Edman degradation.

Example II: Expression of heliomicine in the yeast

5 *Saccharomyces cerevisiae*

All the techniques used below are standard laboratory techniques. The detailed protocols for these techniques have been described in particular in Ausubel et al.

10 Example II-1: Assembling of the synthetic gene

Assembling was carried out using 6 synthetic oligonucleotides encoding the 44 amino acids of heliomicine preceded by the 5 C-terminal amino acids of the pre-pro sequence of factor $\alpha 1$ (Mf $\alpha 1$) of the yeast.

15 The oligonucleotides represented in Figure 1 were
chosen taking into account the preferential codons used by *S. cerevisiae*.

The assembling took place in several steps:

- oligonucleotides 2 to 5 were phosphorylated
20 at their 5' ends by the action of polynucleotide kinase
(New England Biolabs);

- oligonucleotides 1 to 6 were mixed, heated to 100EC and hybridized by slowly reducing the temperature to 25EC over 3 hours;

25 - the hybridized oligonucleotides were
subjected to a treatment with T4 bacteriophage ligase (New England Biolabs) for 15 hours at 15EC;

- the DNA unit resulting from the hybridization of the oligonucleotides which is represented in Figure 1, flanked by the HindIII and BglII restriction sites, was inserted into the plasmid pBluescript SK+ (Stratagene) digested with the enzymes HindIII and BamHI (BglII and BamHI are compatible). The ligation mixture was then used to transform competent *E.coli* DH5 α cells (Stratagene). Several clones were analysed and sequenced. One of these clones which had the desired sequence was called pSEA1.

Example II-2: Construction of the vector pSEA2 which allows the secretion of the heliomicine synthesized

The HindIII-SalI DNA fragment of the vector pSEA1, carrying the sequence encoding heliomicine as well as the SphI-HindIII fragment of the vector M13JM132 (Michaut *et al.*, 1985, FEBS Letters, 395, pp 6-10) were inserted between the SphI and SalI sites of the plasmid pTG4812 (Michaut *et al.*, 1996, FEBS Letters, 395, pp 6-10). The SphI-HindIII fragment of the vector M13JM132 contains the sequence of the promoter of the MF α 1 gene of the yeast as well as the sequence encoding the pre-pro region of factor MF α 1. In the resulting plasmid pSEA2, the synthetic gene for heliomicine therefore finds itself inserted between the pre-pro sequences of factor MF α 1 and the transcription terminator; this construct should therefore ensure the maturation and the secretion of heliomicine.

**Example II-3: Transformation of a strain of
S. cerevisiae with the DNA of the plasmid pSEA2 and
analysis of the transformants**

The yeast strain TGY 48.1 (MATa, ura3-D5,
5 his,pral,prb1,prc1,cps1; Reichhart et al., 1992,
Invert. Reprod. Dev. 21, pp 15-24) was transformed with
the plasmid pSEA2. The transformants were selected at
29EC on a selective YNBG medium (0.67% yeast nitrogen
base, 2% glucose), supplemented with 0.5% of casamino
10 acids and containing no uracil. After transformation,
several yeast clones, selected for the ura⁺ character,
were cultured for 48 h at 29EC in 50 ml of selective
medium. After centrifugation (4000 g, 30 min, 4EC), the
supernatant was acidified to pH 3.5 with acetic acid,
15 before being deposited on a Sep-PakTM C₁₈ cartridge
(Waters Associates) equilibrated with acidified water
(0.05% TFA). The various proteins bound to the
cartridge were eluted with solutions of 0.05% TFA
containing increasing percentages of acetonitrile.

20 The 40% fraction, exhibiting an antifungal
activity, was analysed by HPLC on an Aquapore RP-300 C₈
reversed-phase analytical column (BrownleeTM,
220 H 4.6 mm, 300 Å), using a linear gradient of
acetonitrile from 2% to 40% over 80 min in 0.05% TFA
25 with a constant flow rate of 0.8 ml/min. The fractions
were collected manually by monitoring the variation in
absorbance at 225 nm and 254 nm. The fractions

collected were dried under vacuum, reconstituted with ultrapure water and analysed for their antifungal activity under the conditions described in Example III. The structural characterization of the peptide was
5 carried out as described in Example I.2.

Example II-4: Production of recombinant heliomicine on a semipreparative scale

One of the clones of transformed yeast expressing heliomicine was cultured at 29EC for 24 h in
10 100 ml of selective medium. This procedure was then used to inoculate 4 l of selective medium and the culture was carried out for 48 h at 29EC. The yeasts were removed by centrifugation (4000 g, 30 min, 4EC). The supernatant was acidified to pH 3.5 with acetic
15 acid, subjected to a second centrifugation (4000 g, 30 min, 4EC) before being deposited on a C_{18} preparative reversed-phase open column (Waters Associates), 125 Å, 6 g of phase per 500 ml of supernatant) equilibrated with acidified water (0.05% TFA). The hydrophilic
20 molecules were removed by a wash with acidified water followed by a wash with a 15% solution of acetonitrile prepared in 0.05% TFA. The elution of the peptide was carried out using a 40% acetonitrile solution prepared in 0.05% TFA. The fraction eluted at 40% acetonitrile
25 was lyophilized and then reconstituted in sterile ultrapure water before being subjected to the first purification step.

- first step of purification by HPLC: the purified fraction containing heliomicine was reconstituted in a 25 mM ammonium acetate solution, pH 3.4. This sample was injected into an Aquapore Cation Exchange preparative cation-exchange column (Brownlee™, 250 H 10 mm), using a linear gradient of NaCl from 0% to 100% over 90 min in 25 mM ammonium acetate, pH 3.4 with a constant flow rate of 2 ml/min. The fractions collected were dried under vacuum, reconstituted with ultrapure water and analysed for their antifungal activity under the conditions described below.

- second step of purification by HPLC: the heliomicine was purified to homogeneity by chromatography on an Aquapore RP-300 C₈ semipreparative reversed-phase column (Brownlee™, 220 H 7 mm, 300 Å), using a linear gradient of acetonitrile from 2% to 40% over 80 min in 0.05% TFA with a constant flow rate of 2 ml/min.

Example III: Test of activity in vitro: measurement of the antifungal activity by microspectrophotometry

This methodology was used to test for the antifungal molecules during the various purification steps, for the determination of the activity spectrum of the peptide and for the determination of the minimum inhibitory concentration (MIC) at which the peptide was active. The MIC was expressed as the concentration range [a] - [b] where [a] was the minimum concentration

where the start of growth is observed and [b] the concentration for which no growth was observed. Examples of the specific activity of heliomicine, against filamentous fungi and yeasts, are given in
5 Tables 1 and 2.

Example III-1: Test for detection of activity against filamentous fungi

The antifungal activity was detected by a test for inhibition of growth in a liquid medium. The
10 spores of the fungi to be tested were suspended in a culture medium of the "potato-glucose" type. Preferably, 12 g of Potato Dextrose Broth medium (Difco) were used per 1 l of demineralized water. Two antibiotics were added to the culture medium:
15 tetracycline (final concentration of 10 µg/ml) and cefotaxime (100 µg/ml). 10 µl of each fraction to be analysed are deposited in microtitre plates in the presence of 90 µl of culture medium containing the spores (at a final concentration of 10⁴ spores/ml). The
20 incubation was carried out in a humid chamber at 30°C for 48 hours. Fungal growth was observed under a light microscope after 24 h and quantified after 48 hours by measuring the absorbance at 600 nm with the aid of a spectrophotometric microtitre plate reader.

25 - filamentous fungi tested: *Aspergillus fumigatus* (gift from Dr H. Koenig, Hôpital civil, Strasbourg); *Nectria haemotococca*, *Fusarium culmorum*,

Trichoderma viride (fungus culture collection of the Université Catholique of Leuven, Belgium); *Neurospora crassa*, *Fusarium oxysporum*, (fungus culture collection of Société Clause, Paris).

5 The results of the test of heliomicine activity against filamentous fungi are presented in Table 1 below.

Table 1: activity of heliomicine against
filamentous fungi

Fungi	MIC of heliomicine (μ M)
<i>Neurospora crassa</i>	0.1-0.2
<i>Fusarium culmorum</i>	0.2-0.4
<i>Fusarium oxysporum</i>	1.5-3
<i>Nectria haematococca</i>	0.4-0.8
<i>Trichoderma viride</i>	1.5-3
<i>Aspergillus fumigatus</i>	6-12.5

10

Example III-2: Test for detection of activity against yeasts

The various yeast strains were incubated in a "Sabouraud" type culture medium and incubated at 30EC
15 for 24 h with gentle stirring. The test sample (10 μ l) was deposited in microtitre plate wells to which there were added 90 μ l of a dilute yeast culture whose density was adjusted to OD 600 = 0.001. Growth was evaluated by measuring the absorbance at 600 nm with

the aid of a spectrophotometric microtitre plate reader.

- yeasts tested: *Candida albicans*,
C. glabrata, *C. tropicalis*, *C. krusei*, *C. inconspicua*,
 5 *Cryptococcus neoformans*, *Cryp. albidus*, *Saccharomyces cerevisiae* (gift from Dr H. Koenig, Hôpital civil, Strasbourg).

The results of the test of heliomicine activity against yeasts are presented in Table 2 below.

10 Table 2: activity of heliomicine against yeasts

Yeasts	MIC of heliomicine (μ M)
<i>Candida albicans</i>	2.5-5
<i>Candida tropicalis</i>	2.5-5
<i>Candida krusei</i>	10-20
<i>Candida inconspicua</i>	5-10
<i>Cryptococcus neoformans</i>	2.5-5
<i>Cryptococcus albidus</i>	5-10

These results show the excellent antifungal activity of the peptide according to the invention.

Example IV: Preparation of a transformed plant

15 **comprising a gene encoding heliomicine**

This example describes the preparation of the sequence encoding heliomicine for its expression in a plant cell, of the chimeric gene, of the integrating vector and of the transformed plants. Figures 2 to 6 in

the annexe describe the schematic structures of some plasmids prepared for the construction of the chimeric genes. In these figures, the various restriction sites are marked in *italics*.

5 All the techniques used below are standard laboratory techniques. The detailed protocols for these techniques are in particular described in Ausubel et al.

Example IV-1: Construction of the chimeric genes for
10 the transformation of plants

pRPA-MD-P: Creation of a plasmid containing the signal peptide of the tobacco PR-1 α gene

The two complementary synthetic oligonucleotides Oligo 7 and Oligo 8 below are
15 hybridized at 65EC for 5 minutes and by slow reduction of the temperature to 30EC over 30'.

Oligo 7: 5' GCGTCGACGC GATGGGTTTC GTGCTTTTCT CTCAGCTTCC
ATCTTTCCTT CTTGTGTCTA CTCTTCTTCT TTTCC 3'

Oligo 8: 5' TCGCCGGCAC GGCAAGAGTA AGAGATCACA AGGAAAAGAA
GAAGAGTAGA CACAAGAAGG AAAGATGGAA GC 3'

20

After hybridization between Oligo 7 and Oligo 8, the DNA remaining single-stranded serves as template for the Klenow fragment of *E. coli* polymerase I (under the standard conditions recommended by the manufacturer
25 (New England Biolabs)) for the creation of the double-

stranded oligonucleotide starting from the 3' end of each oligo. The double-stranded oligonucleotide obtained is then digested with the restriction enzymes SacII and NaeI and cloned into the plasmid pBS II SK(-) (Stratagene) digested with the same restriction enzymes. A clone is then obtained which comprises the region encoding the signal peptide of the tobacco PR-1 α gene (SEQ ID NO 4).

pRPA-PS-PR1 α -helio: Creation of a sequence encoding heliomicine fused with the PR-1 α signal peptide with no untranscribed region in 3'

The two synthetic oligonucleotides complementary to Oligo 9 and Oligo 10 sequences according to the operating conditions described for pRPA-MD-P.

Oligo 9: 5' GATAAGCTTA TCGGTTCTG CGTGTGGGGT GCTGTGAACT
ACACTTCCGA TTGCAACGGT GAGTGCAAGA GGAGGGGTTA 3'

Oligo 10: 5' CCGGATCCGT CGACACGTTC GCCTCGCCGA GCTCTCAAGT
CTCGCACCAG CAGTTCACGT TAGCGAAGGA ACCGCAGTGA
CCACCCTTGT AACCCCTCCT CTTGCACTC 3'

After hybridization between Oligo 9 and Oligo 10, the DNA remaining single-stranded serves as template for the Klenow fragment of *E. coli* polymerase I (under the standard conditions recommended by the manufacturer (New England Biolabs)) for the creation of the double-stranded oligonucleotide starting from the

3' end of each oligo. This double-stranded oligonucleotide containing the coding portion of heliomicine (SEQ ID NO 2) is then cloned directly into the plasmid pRPA-MD-P which has been digested with the restriction enzyme NaeI. The correct orientation of the clone obtained is checked by sequencing. A clone is then obtained which comprises the region encoding the PR-1 α -heliomicine fusion protein situated between the NcoI restriction sites at the N-terminal end and the ScaI, SacII and BamHI restriction sites at the C-terminal end (SEQ ID NO 3).

pRPA-RD-239: Creation of a vector for expression in plants comprising the sequence encoding the PR-1 α -heliomicine fusion protein

The plasmid pRTL-2 GUS, derived from the plasmid pUC-19, was obtained from Dr Jim Carrington (Texas A&M University, not described). This plasmid, whose schematic structure is represented in Figure 2, contains the duplicated CaMV 35S promoter isolated from the cauliflower mosaic virus (CaMV 2H35S promoter; Odell et al., 1985) which directs the expression of an RNA containing the tobacco etch virus 5' untranslated sequence (TEV 5' UTR; Carrington & Freed, 1990), the *E. coli* β -glucuronidase gene (GUS Jefferson et al., 1987) followed by the CaMV 35S RNA polyadenylation site (CaMV polyA; Odell et al., 1985).

The plasmid pRTL-2 GUS is digested with the

restriction enzymes NcoI and BamHI and the large DNA fragment is purified. The plasmid pRPA-PS-PR1 α -helio is digested with the restriction enzymes NcoI and BamHI and the small DNA fragment containing the region encoding the PR-1 α -heliomicine fusion protein is purified. The two purified DNA fragments are then ligated together into a cassette for expression in plants which synthesizes a PR-1 α -heliomicine fusion protein. The schematic structure of this expression cassette is represented in Figure 3. "PR-1 α -heliomicine" represents the coding region for the PR-1 α -heliomicine fusion protein of pRPA-RD-239. The heliomicine is transported to the extracellular matrix of the plant by the action of the PR-1 α signal peptide.

pRPA-RD-195: Creation of a plasmid containing a modified multiple cloning site

The plasmid pRPA-RD-195 is a plasmid derived from pUC-19 which contains a modified multiple cloning site. The complementary synthetic oligonucleotides Oligo 11 and Oligo 12 below are hybridized and made double-stranded according to the procedure described for pRPA-MD-P.

Oligo 11: 5' AGGGCCCCCT AGGGTTTAAA CGGCCAGTCA GGCCGAATTC
GAGCTCGGTA CCCGGGGATC CTCTAGAGTC GACCTGCAGG
CATGC 3'

Oligo 12: 5' CCCTGAACCA GGCTCGAGGG CGCGCCTTAA TTAAAAGCTT
GCATGCCTGC AGGTCGACTC TAGAGG 3'

The double-stranded oligonucleotide obtained is then ligated into pUC-19 which has been previously digested with the restriction enzymes EcoRI and HindIII and made blunt-ended using the Klenow fragment of *E. coli* DNA polymerase I. A vector is obtained which contains multiple cloning sites in order to facilitate the introduction of the cassettes for expression in an *Agrobacterium tumefaciens* vector plasmid. The schematic structure of this multiple cloning site is represented in Figure 4.

pRPA-RD-240: Introduction of the cassette for expression of PR-1 α -heliomicine from pRPA-RD-239 into pRPA-RD-195

The plasmid pRPA-RD-239 is digested with the restriction enzyme PstII. The DNA fragment containing the cassette for expression of PR-1 α -heliomicine is purified. The purified fragment is then ligated into pRPA-RD-195 which has been previously digested with the restriction enzyme PstII and dephosphorylated with calf intestinal phosphatase.

pRPA-RD-174: Plasmid derived from pRPA-BL-150A (EP 0,508,909) containing the gene for tolerance to bromoxynil of pRPA-BL-237 (EP 0,508,909)

The gene for tolerance to bromoxynil is isolated from pRPA-BL-237 by gene amplification by PCR. The fragment obtained is blunt-ended and is cloned into the EcoRI site of pRPA-BL-150A which has been made

blunt-ended by the action of Klenow polymerase under standard conditions. An *Agrobacterium tumefaciens* vector is obtained which contains the gene for tolerance to bromoxynil near its right border, a gene
 5 for tolerance to kanamycin near its left border and a multiple cloning site between these two genes.

The schematic structure of pRPA-RD-174 is represented in Figure 5. In this figure, "nos" represents the *Agrobacterium tumefaciens* nopaline
 10 synthase polyadenylation site (Bevan et al., 1983), "NOS pro" represents the *Agrobacterium tumefaciens* nopaline synthase promoter (Bevan et al., 1983), "NPT II" represents the *E. coli* Tn5 transposon neomycin phosphotransferase gene (Rothstein et al., 1981), "35S
 15 pro" represents the 35S promoter isolated from the cauliflower mosaic virus (Odell et al., 1985), "BRX" represents the nitralase gene isolated from *K. ozaenae* (Stalker et al., 1988), "RB" and "LB" represent the right and left borders respectively of the sequence of
 20 an *Agrobacterium tumefaciens* Ti plasmid.

pRPA-RD-184: Addition of a new unique restriction site into pRPA-RD-174

The complementary synthetic oligonucleotides Oligo 13 and Oligo 14 below are hybridized and made
 25 blunt-ended according to the procedure described for pRPA-MD-P.

Oligo 13: 5' CCGGCCAGTC AGGCCACACT TAATTAAGTT TAAACGCGGC
 CCCGGCGCGC CTAGGTGTGT GCTCGAGGGC CCAACCTCAG
 TACCTGGTTC AGG 3'

Oligo 14: 5' CCGGCCTGAA CCAGGTACTG AGGTTGGGCC CTCGAGCACA
 CACCTAGGCG CGCCGGGGCC GCGTTTAAAC TTAATTAAGT
 GTGGCCTGAC.TGG 3'

The hybridized double-stranded
 5 oligonucleotide (95 base pairs) is purified after
 separation on an agarose gel (3% Nusieve, FMC). The
 plasmid pRPA-RD-174 is digested with the restriction
 enzyme XmaI, and the large DNA fragment is purified.
 The two DNA fragments obtained are then ligated.

10 A plasmid derived from pRPA-RD-174 is
 obtained which comprises other restriction sites
 between the gene for tolerance to bromoxynil and the
 selectable marker kanamycin gene.

The schematic structure of the plasmid pRPA-
 15 RD-184 is represented in Figure 6 where the terms
 "nos", "NPT-II", "NOS pro", 35S pro", "BRX gene", "RB"
 and "LB" have the same meaning as in Figure 5.

**pRPA-RD-241: Creation of an *Agrobacterium tumefaciens*
 vector containing the construct of the gene encoding
 20 heliomicine directed towards the extracellular matrix**

The plasmid pRPA-RD-240 is digested with the
 restriction enzymes SfiII and AscI and the DNA fragment
 containing the PR-1 α -heliomicine gene is purified. The
 plasmid pRPA-RD-184 is digested with the same

restriction enzymes. The DNA fragment containing the cassette for expression of PR-1 α -heliomicine is then ligated into pRPA-RD-184. An *Agrobacterium tumefaciens* vector is thus obtained which contains the sequence
5 encoding the PR-1 α -heliomicine fusion protein which leads to the expression of heliomicine in the extracellular matrix of the plant.

IV-2: Preparation of transformed tobacco

10 2.1 - Transformation

The vector pRPA-RD-241 is introduced into the *Agrobacterium tumefaciens* EHA101 strain (Hood et al., 1987) carrying the cosmid pTVK291 (Komari et al., 1986). The transformation technique is based on the
15 procedure of Horsh et al. (1985).

2.2- Regeneration

The regeneration of the PBD6 tobacco (origin SEITA France) from foliar explants is carried out on a Murashige and Skoog (MS) basic medium comprising 30 g/l
20 of sucrose as well as 200 μ g/ml of kanamycin. The foliar explants are collected from plants cultivated in a greenhouse or *in vitro* and regenerated according to the foliar disc technique (Horsh et al., 1985) in three successive stages: the first comprises the induction of
25 shoots on a medium supplemented with 30 g/l of sucrose containing 0.05 mg/l of naphthylacetic acid (ANA) and 2 mg/l of benzylaminopurine (BAP) for 15 days. The

shoots formed during this stage are then developed for 10 days by culturing on an MS medium supplemented with 30 g/l of sucrose but containing no hormone. Next, developed shoots are collected and they are cultivated
5 on an MS rooting medium containing half the content of salt, vitamins and sugar and containing no hormone. After about 15 days, the rooted shoots are transferred into soil.

2.3- Tolerance to bromoxynil

10 Twenty transformed plants have been regenerated and placed in the greenhouse for the pRPA-RD-241 construct. These plants have been treated in the greenhouse, at the 5 leaves stage, with a Padner aqueous suspension corresponding to 0.2 kg of
15 bromoxynil as active substance per hectare.

All the plants exhibiting a complete tolerance to bromoxynil are then used in different experiences demonstrating that heliomicine expression in transformed plants makes them more resistant to fungal
20 infections.

Example V: example of formulations comprising heliomicine

In all the examples of formulation below, active
25 substance is intended to designate the heliomicine specified by formula I according to the invention, and un particular heliomicine prepared according to the

above examples.

Example V-1: emulsifiable concentrates

Example EC1:

-active substance	400 g/l
-alkali metal dodecylbenzenesulphonate	24 g/l
-oxyethylated nonylphenol containing 10 molecules of ethylene oxide	16 g/l
-cyclohexanone	200 g/l
-aromatic solvent	qs 1 litre

Example EC2:

-active substance	250 g
-epoxidized vegetable oil	25 g
-mixture of alkylarylsulphonate and polyglycol ether and fatty alcohols	100 g
-dimethylformamide	50 g
-xylene	575 g

Example V-2: flowableExample F 1:

-active substance	500 g
-polyethoxylated tristyrylphenol phosphate	50 g/l
-polyethoxylated alkylphenol	50 g
-sodium carboxylate	20 g
-ethylene glycol	50 g
-organopolysiloxane oil (antifoam)	1 g
-polysaccharide	1.5 g
-water	316.5 g

Example V-3: wettable powders (or spraying powders):Example WP 1

-active substance	50%
-ethoxylated fatty alcohol (wetting agent)	2.5%
-ethoxylated phenylethylphenol (dispersing agent)	5%
-chalk (inert carrier)	42.5%

Example WP 2:

-active substance	10%
-C13, branched type oxo synthetic alcohol ethoxylated with 8 to 10 ethylene oxide (wetting agent)	0.75%
-neutral calcium lignosulphonate (dispersing agent)	12%
-calcium carbonate (inert filler)	qs 100%

Example WP 3:

-active substance	75%
-wetting agent	1.50%
-dispersing agent	8%
-calcium carbonate (inert filler)	qs 100%

Example WP 4:

-active substance	90%
-ethoxylated fatty alcohol (wetting agent)	4%
-ethoxylated phenylethylphenol (dispersing agent)	6%

Example WP 5:

-active substance	50%
-mixture of anionic and nonionic surfactants (wetting agent)	2.5%
-sodium lignosulphonate (dispersing agent)	5%
-kaolinic clay (inert carrier)	42.5%

Example V-4: dispersible granulesExample DG 1

- 5 90% by weight of active substance and 10% of
 pearl urea are mixed in a mixer. The mixture is then
 ground in a toothed roll grinder. A powder is obtained
 which is wetted with about 8% by weight of water. The
 wet powder is extruded in a perforated roll extruder.
- 10 Granules are obtained which are dried and then crushed
 and sieved so as to retain respectively only the

granules having a size of between 150 and 2000 microns.

Example DG2:

The following constituents are mixed in a mixer:

-active substance	75%
-wetting agent (sodium alkylnaphthalenesulphonate)	2%
-dispersing agent (sodium polynaphthalenesulphonate)	8%
-inert filler insoluble in water (kaolin)	15%

This mixture is granulated on a fluidized bed, in the presence of water, and then dried, crushed
5 and sieved so as to obtain granules having a size of between 0.15 and 0.80 mm.

Example V-5: pharmaceutical compositions

Example A: tablets

Tablets containing 50 mg doses of active
10 peptide having the following composition are prepared according to the usual technique:

- peptide heliomicine M1	50 mg
- starch	60 mg
- lactose	50 mg
- magnesium stearate	2 mg

Example B: injectable solution

An injectable solution containing 20 mg of
15 active peptide having the following composition is

prepared:

- peptide heliomicine M 2	22.4 mg
- distilled water	qs 2 cm ³

CLAIMS

5 Xaa-Cys-Xab-Cys-Xac-Cys-Xad-Cys-Xae-Cys-Xaf-Cys-Xag

in which:

Xab is a peptide residue comprising from 1 to 10 amino acids, preferably 10,

Xac is a peptide residue of 3 amino acids,

15 Xad is a peptide residue comprising from 1 to
9 amino acids, preferably 9,

Xae is a peptide residue comprising from 1 to 7 amino acids, preferably 7,

Xaf is a peptide residue of 1 amino acid, and

20 Xag is -OH or a peptide residue comprising
from 1 to 5 amino acids, preferably 1 or 2 amino acids.

2. Peptide according to claim 1,
characterized in that

Xaa represents the following peptide sequence Xaa'-Gly-Xaa"- in which Xaa' represents NH₂ or a peptide residue comprising 1 to 9 amino acids, preferably 1 to 5 amino acids, and Xaa" represents a peptide residue comprising
5 at least one amino acid, preferably chosen from Leu, Ile, Val, Pro, Ser or Thr, and/or

Xab represents the following peptide sequence -Val-Xab'-Asp-, in which Xab' represents a peptide residue comprising from 0 to 8 amino acids, preferably 8,
10 and/or

Xac represents the following peptide sequence -Asn-Xac'-Glu-, in which Xac' represents a peptide residue comprising one amino acid, and/or

Xad represents the following peptide sequence -Lys-Xad'-Gly-His-, in which Xad' represents a peptide residue comprising from 0 to 6 amino acids, preferably 6, and/or

Xae represents the following peptide sequence -Gly-Xae'-Asn-, in which Xae' represents a peptide residue comprising from 0 to 5 amino acids, preferably 5, and/or

Xaf represents one of the following amino acids Trp, Phe, Leu, Ile or Val and/or

Xag represents the following peptide sequence -Glu-Xag' in which Xag' represents OH or a variable residue having a sequence comprising from 1 to 4 amino acids, preferably 1 amino acid.

3. Peptide according to claim 1 or 2,
characterized in that Xaa or Xaa' comprise at least one
basic amino acid, and/or Xad or Xad' comprise at least
5 one basic amino acid.

4. Peptide according to claim 3,
characterized in that Xad or Xad' comprise 1, 2, 3 or 4
basic amino acids.

5. Peptide according to either of claims 3
10 and 4, characterized in that the basic amino acids are
chosen from lysine, arginine or homoarginine.

6. Peptide according to one of claims 1 to
5, characterized in that
Xaa represents the following peptide sequence NH₂-Asp-
15 Lys-Leu-Ile-Gly-Ser-, and/or
Xab represents the following peptide sequence -Val-Trp-
Gly-Ala-Val-Asn-Tyr-Thr-Ser-Asp-, and/or
Xac represents the following peptide sequence -Asn-Gly-
Glu-, and/or
20 Xad represents the following peptide sequence -Lys-Arg-
Arg-Gly-Tyr-Lys-Gly-Gly-His-, and/or
Xae represents the following peptide sequence -Gly-Ser-
Phe-Ala-Asn-Val-Asn-, and/or
Xaf represents the following amino acid Trp- and/or
25 Xag represents the following peptide sequence -Glu-Thr-
OH.

7. Peptide according to one of claims 1 to 6, characterized in that it is represented by the identifier No. 2 (SEQ ID NO 2).

8. Peptide according to one of claims 1 to 7, characterized in that it comprises at either of its ends, or at both ends, peptide residues necessary for its expression and targeting in a host organism.

9. Peptide according to one of claims 1 to 8, characterized in that the cysteine residues of the peptide of formula (I) form at least one intramolecular disulphide bridge.

10. "Peptide-heliomicine" fusion peptide, characterized in that the heliomicine is a peptide defined according to one of claims 1 to 9.

11. Fusion peptide according to claim 10, characterized in that the peptide fused with heliomicine is a signal peptide or a transit peptide.

12. Fusion peptide according to claim 11, characterized in that the transit peptide is the signal peptide of the tobacco PR-1 α gene or the precursor of factor Mat alpha 1.

13. Fusion peptide according to claim 12, characterized in that it is represented by the sequence identifier No. 1 (SEQ ID NO 1) or the sequence identifier No. 3 (SEQ ID NO 3).

14. As a medicament, the peptide according to one of claims 1 to 13.

15. Composition, characterized in that it comprises the peptide according to one of claims 1 to 13 and an appropriate vehicle.

16. Nucleic acid fragment, characterized in
5 that it comprises a nucleic acid sequence encoding a peptide according to one of claims 1 to 13.

17. Nucleic acid fragment according to claim 16, characterized in that it is a nucleotide sequence of the DNA type.

10 18. Nucleic acid fragment according to claim 17, characterized in that the nucleotide sequence of the DNA type comprises the DNA sequence described by bases 16 to 147 of the sequence identifier No. 1 (SEQ ID NO 1), by the sequence identifier No. 2 (SEQ ID NO
15 2), a homologous sequence or a sequence complementary to the said sequence.

19. Nucleic acid fragment according to claim 17, characterized in that the nucleotide sequence of the DNA type comprises the DNA sequence described by
20 sequence identifier No. 1 (SEQ ID NO 1), or by the sequence identifier No. 3 (SEQ ID NO 3), a homologous sequence or a sequence complementary to the said sequence.

20. Chimeric gene comprising a coding sequence as well as heterologous regulatory elements at the 5' and 3' positions capable of functioning in a host organism, in particular plants, characterized in
5 that the coding sequence comprises at least one DNA fragment as defined in claims 16 to 19.

21. Chimeric gene according to claim 20, characterized in that the host organism is a microorganism.

10 22. Chimeric gene according to claim 20, characterized in that the host organism is chosen from plant cells and plants.

23. Cloning or expression vector for the transformation of a host organism, characterized in
15 that it comprises at least one replication origin and at least one chimeric gene as defined in claims 20 to 22.

24. Vector according to claim 23, characterised in that it is a virus which may be used
20 for the transformation of developed plants and which contains in addition its own elements for replication and expression.

25. Vector according to claim 23, characterised in that it is a plasmid.

26. Transformed host organisms, characterized in that they contain a nucleic acid fragment according to claims 16 to 19, or a chimeric gene according to claims 20 to 22.

5 27. Transformed host organism according to claim 26, characterized in that it includes microorganisms, plant cells or plants.

 28. Transformed host organism according to claim 27, characterized in that it is a plant
10 containing transformed cells.

 29. Host organism according to claim 28, characterized in that the plant is regenerated from transformed cells.

 30. Transformed host organism according to
15 claim 27, characterized in that the microorganism is chosen from bacteria, in particular *E. coli*, yeasts, in particular of the genera *Saccharomyces* or *Kluyveromyces*, *Pichia*, fungi, in particular *Aspergillus*, or baculoviruses.

20 31. Transformed plant cell, characterized in that it contains a nucleic acid fragment according to claims 16 to 19 or a chimeric gene according to claims 20 to 22.

 32. Transformed plant resistant to diseases,
25 characterized in that it comprises at least one transformed plant cell according to claim 31.

33. Transformed plant according to claim 32, characterized in that it is resistant to diseases caused by *Cercospora*, in particular *Cercospora beticola*, *Cladosporium*, in particular *Cladosporium herbarum*, *Fusarium*, in particular *Fusarium culmorum* or *Fusarium graminearum*, or by *Phytophthora*, in particular *Phytophthora cinnamomi*.

34. Transformed plant resistant to diseases, characterized in that it is derived from the cultivation and/or crossing of the plants according to either of claims 32 and 33.

35. Seeds of transformed plants according to one of claims 32 to 34.

36. Method of transforming host organisms, in particular plant cells or plants, characterized in that at least one nucleic acid fragment according to claims 16 to 19 or a chimeric gene according to one of claims 20 to 22 is inserted into the said host organism.

37. Method of transforming plants to make them resistant to fungal or bacterial diseases, characterised in that at least one nucleic acid fragment according to claims 16 to 19 or a chimeric gene according to one of claims 20 to 22 is inserted into the said host organism.

38. Method of cultivating transformed plants according to one of claims 32 to 35, characterized in that it consists in planting the seeds of the said transformed plants in a plot of a field appropriate for
5 cultivating the said plants, in applying to the said plot of the said field an agrochemical composition, without substantially affecting the said seeds or the said transformed plants, then in harvesting the cultivated plants when they arrive at the desired
10 maturity and optionally in separating the seeds from the harvested plants.

39. Method of cultivation according to claim 38, characterized in that the agrochemical composition comprises at least one active product having at least
15 one fungicidal and/or bactericidal activity.

40. Method of cultivation according to claim 39, characterized in that the active product exhibits an activity which is complementary to that of the peptide according to one of claims 1 to 13.

20 41. Method of preparing heliomicine defined according to one of claims 1 to 13, characterized in that it comprises the steps of culturing a transformed organism according to one of claims 26 or 30 in an appropriate culture medium, followed by the extraction
25 and total or partial purification of the heliomicine obtained.
